

The private-rule payoff contrast is type-specific

Closed-form slice $l = 0.50 \times h$; $m = 4$ weak states; $\beta = 0.90$

Colored regions compare the hegemon's private-information payoff under unanimity and majority at the same parameter point. The hatched region is empty because unanimity has no perfect Bayesian equilibrium in pure ballot strategies. The left-edge segment is the literal $p = 0$ endpoint. The horizontal threshold $m \times h = 1$ is the cost at which majority switches between buying the hegemon and buying an additional weak-state vote. No prior-weighted or ex ante image is displayed. Note: model-generated closed-form regions.
